

1. Brainstorming & Ideation

Project foundation and problem definition

Project Title

Import Data Using Transform Maps (Spreadsheet)

Project Overview

This micro project demonstrates how structured employee data from an Excel spreadsheet can be loaded into ServiceNow using Import Sets and processed into a target table using a Transform Map. The workflow includes field mapping, transformation, validation, and duplicate handling with Coalesce.

Problem Statement

Employee information may arrive in spreadsheets and require bulk entry into a platform. Manual record creation can be slow and prone to entry mistakes. The project explores a repeatable import workflow that stages spreadsheet rows, maps source columns to target fields, and inserts or updates records.

Objectives

- Prepare a structured employee spreadsheet for import.
- Create a custom target table and an Import Set staging table.
- Configure a Transform Map and map source fields to target fields.
- Execute transformation and verify the resulting records.
- Enable Coalesce to update matching employee records and avoid duplicates.
- Create reports and a dashboard to present employee data.

Scope

The demonstration uses sample employee data and a custom Employee Test table. It covers spreadsheet loading, transformation, record validation, duplicate/update behavior, and basic reporting. Production integrations, access-control design, and enterprise-scale data governance are outside the demonstrated scope.

Expected Outcomes

- A populated Employee Test table from spreadsheet rows.
- Verified field mappings and transformation status.
- Demonstrated insert/update/ignored behavior when reimporting data.
- Three reports and a dashboard based on the employee table.

Proposed Solution

Use ServiceNow Load Data to stage the spreadsheet in Employee Import, then run the Sample Spreadsheet Import Transform Map targeting Employee Test. Set Employee ID as the coalesce key for repeat imports, and validate outcomes in the target list and Transform History.
